# Methods/Criteria of Project Evaluation or Measures of project Worth of Investment 

Dr. A.K. Sarma<br>Professor, Agril. Economics, FA, AAU, Jorhat.

Project :
A project is an investment activity where we expend capital resources to create a producing asset from which we can expect to realize benefits over an extended period of time. Or a project is an activity on which we will spend money in expectation of returns and which logically seems to lend itself to planning, financing and implementation as a unit. A project should have the following characteristics.

1. It should have a specific starting point and specific ending point.
2. Its major costs and returns are measurable
3. It should have a specific geographic location
4. It should have a specific clientele group
5. It should have a well-defined time sequence of investment and production activities.

## Methods/Criteria of Project Evaluation:

The methods/criteria more often used for evaluating a project are (1) Simple rate of return (SRR) (2) Payback Period (PBP) (3) Benefit Cost Ratio (BCR) (4) Net present Value (NVP) or Net Present Worth (NPW) and (5) Internal Rate of Return (IRR). The SRR and the PBP are the undiscounted measures while BCR, NPV and IRR are the discounted measures of project worth of Investment. A discussion on the following methods are given below:

## Simple Rate of Return:

The SRR is a commonly used criterion of project evaluation. It basically expresses the average net profits (Net Cash Flows) generated each year by an investment as a percentage of investment over the investment's expected life. It is as

$$
S R R=Y / I
$$

Where
$\mathrm{Y}=$ the average annual net profit (after allowing depreciation) from the investment
I = the initial investment
The calculated SRR should be compared with the investor's Required Rate of Return (RRR) to judge the profitability of the investment. The investment will be accepted if SRR.RRR, otherwise it will be rejected. When the SRR of all the investment opportunities is greater than the RRR of the investor, then the investment yielding the highest SRR should be selected.

## Pay Back Period (PBP)

The Pay back period is the length of time required for an investment to pay itself out. It is computed as
PBP = I/E

When the projected net cash flows (E) are uniform or

$$
P B P=I / \sum_{t=1}^{n} E n=1
$$

When the projected net cash flows are non-uniform.

Where I = the initial investment.
$E=$ the projected net cash flows per year from the investment.
PBP = Pay Back Period expressed in number of years.
Individual investments are ranked according to their relative pay back period with the shortest being the most favored. The acceptability of the investment is determined by comparison with the investor's required pay back period (RPP). Accept the investment when the PBP<RPP, otherwise reject the investment. Although it is simple and easy to use, the PBP method has two major weaknesses as a measure of investment worth.
(1) this method fails to consider earnings after the pay back period is sreached..
(2) it fails to consider the difference in timing of cash flows.

## Benefit Cost Ratio (BCR)

It is the ratio of present worth of benefit stream to present worth of cost stream i.e.

$$
B C R=\frac{\text { Sum of the present worth of benefit }}{\text { Sum of the present worth of cost }}
$$

Mathematically, it can be shown as

$$
B C R=\frac{\sum_{t=1}^{n} B n /(1+i)^{n}}{\sum_{t=1}^{n} C n /(1+i)^{n}}
$$

Where,

$$
\begin{aligned}
\mathrm{Bn} & =\text { Benefit in each year } \\
\mathrm{Cn} & =\text { Cost in each year } \\
\mathrm{n} & =\text { number of year } \\
\mathrm{i} & =\text { interest (discount) rates. }
\end{aligned}
$$

The investment is said to be profitable when the BCR is one or greater than 1. This method is widely used in economic analysis and not in private investment analysis.

## Net Present Value (NVP)

Net present value is computed by finding the difference between the present worth of benefit stream less the present worth of cost stream. Or it is simply the present worth of the cash flow stream since it is a discounted cash flow measure of project worth along with internal rate of return.

NPV = Present worth of Benefit Stream - Present Worth of Cost Stream.
Mathematically, it can be shown as

$$
N P V=\sum_{i=1}^{n} B n /(1+i)^{n}-=\sum_{t=1}^{n} C n /(1+i)^{n}
$$

Or NPV = Present worth of the cash flow stream.
Mathematically,

$$
N P V=\sum_{t=1}^{n}(B n-C n) /(1+i)^{n}
$$

Where,
$\mathrm{Bn}=$ benefits in each year of the project.
$\mathrm{Cn}=$ Costs in each year of the project.
$\mathrm{n}=$ number of years in a project
$\mathrm{i}=$ interest (discount) rate
$\mathrm{Bn}-\mathrm{Cn}=$ Cash flow in $\mathrm{n}_{\mathrm{th}}$ year of the project
The project is profitable or feasible if the calculated NVP is positive when discounted at the opportunity cost of capital.

## Internal Rate of Return (IRR)

Internal Rate of Return (IRR) is that discount rate which just makes the net present value (NVP) of the cash flow equal zero. It is considered to be the most useful measure of project worth and used by almost all the institutions including World Bank in economic and financial analysis of the project. It represents the average earning power of the money used in the project over the project life. It is also sometimes called yield of the investment.

Mathematically,
IRR is that discount rate ' $i$ ' such that

$$
\sum_{t=1}^{n}(B n-C n) /(1+i)^{n}=0 \text { i.e. } N V P=0
$$

where

$$
\mathrm{Bn}=\text { Costs in each year of the project. }
$$

$\mathrm{Cn}=$ Costs in each year of the project.
$\mathrm{n}=$ number of years in the project.
$\mathrm{i}=$ interest (discount) rate.
A project is profitable or feasible for investment when the internal rate of return is higher than the opportunity cost of capital.

The computation of IRR for project involves a trial and error method. Here alternative discount rates are used to the cash flow streams of the project under consideration till the NPV of the project reaches zero. However, it is not always possible to get a discount rate which makes the NPV exactly equal to zero through this trial and error method. We may get discount rate, which makes the NPV nearer to zero i.e. either positive or negative. Under such situation, we use interpolation to estimate the true value. Interpolation is simply finding the intermediate value between too discount rates we have chosen.

The rule for interpolating the value of the internal rate of return lying between two discount rates too high on the one side and the too low on the other is.

IRR = Lower discount rate _ Difference between the two discount rates (NPV at lower discount rate : Absolute difference between the NPVs of the two discount rates)

## Results of the methods of evaluation for an investment in 1 hectare of Small Tea

 CultivationSimple Rate of Return (SRR) = Average Annual Profit : Initial Investment<br>Again Average Annual profit $=($ Total Net Cash flows excluding depreciation less Initial Investment) : Investment life<br>$=($ Rs. $1072725.00-$ Rs. 64699.00 30) : 30<br>= Rs. 1008026.00: 30

Rs. 33601.00

Hence, SRR = Average Annual profit $\div$ Initial Inestment
$=$ Rs. $33601.00 \div$ Rs. 64699.00
= 51.93 \%
= 52 \%

## Payaback Period:

PBP $=$ Initial Investment $\div \Sigma$ Net Cash flows $=1$

| Year | Net Cash flows | Cumulative cash flows |
| :---: | :---: | :---: |
| $\mathbf{1}^{\text {st }}$ | 0 | 0 |
| $2^{\text {nd }}$ | 0 | 0 |
| $3^{\text {rd }}$ | -2916.00 | -2916.00 |
| $\mathbf{4}^{\text {th }}$ | 8652.00 | 5736.00 |
| $5^{\text {th }}$ | 17973.00 | 23709.00 |
| $\mathbf{6}^{\text {th }}$ | 27440.00 | 51149.00 |
| $7^{\text {th }}$ | 37256.00 | 88405.00 |

The payback period will be 6 years plus a fraction of a year. To calculate the fraction, we are required to simply divide the amount of funds needed to recover the investment in the $7^{\text {th }}$ year by the amount of cash flows in the year.

Thus, the amount-recovered upto $6^{\text {th }}$ year is Rs.51149.00. The balance amount required to recover the investment (Rs.64699.00) will be Rs.13550.00 (Rs. 64699.00 - Rs. 51149.00 ). The amount of Net cash flows in the $7^{\text {th }}$ year is Rs.37256.00 The pay back fraction then will be Rs. $13350.00 \div$ Rs. $37256.00=0.36$. Hence, the payback period for the investment in 1 hectare of Small Tea Cultivation is estimated as 6.36 years.

## Benefit Cost Ratio @ 15\% Discount Rate:

= Discounted Benefit $\div$ Discounted cost
$=$ Rs. $217472.151 \div$ Rs. 131712.101
$=1.651$.

## Net Present Value @ 15\% Discount Rate:

= Discounted Benefit - Discounted cost
= Rs. 217472.151 - Rs. 131712.101
= Rs. 85760.05
Or Net Present Value @ 15\% Discount Rate:
= Discounted Cash flows only
= Rs. 85760.00
Internal Rate of Return (IRR) :
IRR = Lower discount rate + Difference between the two discount rates (NPV at lower discounted rates / Absolute difference between the NPVs of the two discount rates).

$$
\begin{aligned}
& =25+(30-25) \times\{8855.406 \div(8855.406-(6751.516)\} \\
& =25+5 \times\{8855.406 \div(8855.406-(6751.516\} \\
& =25+5 \times \theta .5674 \\
& =25+2.83701 \\
& =27.84 \%
\end{aligned}
$$

Conclusion : The investment in Small Tea Cultivation is profitable since SRR is very high ( $52 \%$ ), BCR @ $15 \%$ discount rate is greater than 1 (i.e. 1.651), NPV @ $15 \%$ discount rate is +ve (i.e. Rs.85760.05) and IRR is $27.84 \%$. Besides, the Payback Period is also very short (i.e. 6.36 years.).
